Why a Calculus for Concurrency?

- The *Calculus for Communicating Systems* (CCS) was developed by R. Milner around the 80's.
- Other Process Calculi were proposed at about the same time: the *Theory of Communicating Sequential Processes* by T. Hoare and the *Algebra of Communicating Processes* by J. Bergstra and J.W. Klop.
- Researchers were looking for a calculus with few, orthogonal mechanisms, able to represent all the relevant concepts of concurrent computations. More complex mechanisms should be built by using the basic ones.
 - To help understanding / reasoning about / developing formal tools for concurrency.
 - To play a role, for concurrency, like that of the λ -calculus for sequential computation.

Inadequacy of standard models of computations

The λ calculus, the Turing machines, etc. are computationally complete, yet do not capture the features of concurrent computations like

- Interaction and communication
- Inadequacy of functional denotation
- Nondeterminism

Note: nondeterminism in concurrency is different from the nondeterminism used in Formal Languages, like for instance the Nondeterministic Turing Machines.

A few words about nondeterminism

Introduction

A few words about nondeterminism

In standard computation theory, if we want to compute the partial function f s.t. f(0) = 1, a Turing Machine like this one is considered ok

However, we would not be happy with a coffee machine that behaves in the same way

Introduction Syntax and Operational Semantics of CCS 0000000

Nondeterminism in sequential models

- Convenient tool for solving certain problems in an easy way or for characterizing complexity classes (examples: search for a path in a graph, search for a proof etc.)
- Examples of nondeterministic formalisms:
 - The nondeterminismistic Turing machines
 - Logic languages like Prolog and λ Prolog
- The characteristics of nondeterminism in this setting:
 - It can be eliminated without loss of computational power by using backtracking.
 - Failures don't matter: all what we are interested on is the existence of succesful computations. A failure is reported only if all possible alternatives fail.

In standard computation theory, if we want to compute the partial function f s.t. f(0) = 1, a Turing Machine like this one is considered ok

However, we would not be happy with a coffee machine that behaves in the same way

Nondeterminism in concurrent models

- Nondeterminism may arise because of interaction between processes.
- The characteristics of nondeterminism in this setting:
 - It cannot be avoided. At least, not without loosing essential parts of expressive power. All interesting models of concurrency cope with nondeterminism.
 - Failures do matter. Chosing the wrong branch might bring to an "undesirable situation". Backtracking is usually not applicable (or very costly), because the control is distributed: we should restart not one but several processes.
- Hence controlling nondeterminism is very important. In sequential programming is just a matter of efficiency, here is a matter of avoiding getting stuck in a wrong situation.

5

Principles in CCS design

The basic kind of interaction (1/2)

- A calculus should contain only the primary constructs. For instance, the primary form of interaction. *But what is the primary form of interaction?*
- In general, concurrent languages can offer various kinds of communication. For instance:
 - Communications via shared memory.
 - Communication via channels.
 - Communication via broadcasting.
- and we could make even more distinctions
 - one-to-one / one-to-many
 - Ordered / unordered (i.e. queues / bags)
 - Bounded / unbounded.
- So what is the basic kind of communication?
- For CCS the answer was: none of the above!

Principles in CCS design

The basic kind of interaction (2/2)

- In CCS, the fundamental model of interaction is *synchronous* and *symmetric*, i.e. the partners act at the same time performing complementary actions.
- This kind of interaction is called *handshaking*: the partners agree simoultaneously on performing the two (complementary) actions.
- In Java there is a separation between active objects (threads) and passive objects (resources). CCS avoids this separation: Every (non-elementary) entity is a process.
- For instance, consider two proceesses *P* and *Q* communicating via a buffer *B*. in CCS also *B* is a process and the communication is between *P* and *B*, and between *Q* and *B*.

- (channel, port) names: a, b, c, \ldots
- co-names: $\bar{a}, \bar{b}, \bar{c}, \dots$ Note: $\bar{\bar{a}} = a$
- silent action: au
- actions, prefixes: $\mu ::= a \mid \bar{a} \mid \tau$

```
• processes: P, Q ::= 0 inaction

| \mu.P \text{ prefix}

| P | Q \text{ parallel}

| P+Q \text{ (external) choice}

| (\nu a)P \text{ restriction}

| rec_{K}P \text{ process } P \text{ with definition } K = P

| K \text{ (defined) process name}
```

Labeled transition System

Labeled transition system

• The semantics of CCS is defined by in terms of a *labeled* transition system, which is a set of triples of the form

 $P \xrightarrow{\mu} Q$

- Meaning: *P* evolves into *Q* by making the action μ .
- The presence of the label μ allows us to keep track of the interaction capabilities with the environment.

Syntax and Operational Semantics of CCS 0**00**0000 Labeled transition System Some examples a.0 | a.0 (v a) (a.0 | a.0) The restriction can be used to enforce synchronization 0 | a.0 C a.0 | 0 The parallel operator 0 0 may cause infinitely (va) (0 | 0) many different states rec, a.k | a.k The fragment of the rec, a.k + b.0 calculus without parallel

Labeled transition System

Structural operational semantics

The transitions of CCS are defined by a set of inductive rules. The system is also called structural semantics because the evolution of a process is defined in terms of the evolution of its components.

$$\begin{bmatrix} \operatorname{Act} \end{bmatrix} \frac{\mu \cdot P \stackrel{\mu}{\to} P}{\mu \cdot P \stackrel{\mu}{\to} P} \qquad \begin{bmatrix} \operatorname{Res} \end{bmatrix} \frac{P \stackrel{\mu}{\to} P'}{(\nu a)P \stackrel{\mu}{\to} (\nu a)P'}$$
$$\begin{bmatrix} \operatorname{Sum1} \end{bmatrix} \frac{P \stackrel{\mu}{\to} P'}{P + Q \stackrel{\mu}{\to} P'} \qquad \begin{bmatrix} \operatorname{Sum2} \end{bmatrix} \frac{Q \stackrel{\mu}{\to} Q'}{P + Q \stackrel{\mu}{\to} Q'}$$
$$\begin{bmatrix} \operatorname{Par1} \end{bmatrix} \frac{P \stackrel{\mu}{\to} P'}{P|Q \stackrel{\mu}{\to} P'|Q} \qquad \begin{bmatrix} \operatorname{Par2} \end{bmatrix} \frac{Q \stackrel{\mu}{\to} Q'}{P|Q \stackrel{\mu}{\to} P|Q'}$$
$$\begin{bmatrix} \operatorname{Com} \end{bmatrix} \frac{P \stackrel{a}{\to} P' \quad Q \stackrel{\overline{a}}{\to} Q'}{P|Q \stackrel{\tau}{\to} P'|Q'} \qquad \begin{bmatrix} \operatorname{Rec} \end{bmatrix} \frac{P[\operatorname{rec}_{K} P/K] \stackrel{\mu}{\to} P'}{\operatorname{rec}_{K} P \stackrel{\mu}{\to} P'}$$

Introduction What equivalence for CCS? Syntax and Operational Semantics of CCS 0000000

Motivation

14

- It is important to define formally when two system can be considered equivalent
- There may be various "interesting" notion of equivalence, it depends on what we want (which observables we want to preserve)
- A good notion of equivalence should be a congruence, so to allow modular verification

13

Introduction

What equivalence for CCS?

Examples: possible definitions of a coffee machine

- $\operatorname{rec}_{K} \operatorname{coin.}(\operatorname{coffee.} \overline{\operatorname{ccup}}.K + \operatorname{tea.} \overline{\operatorname{tcup}}.K)$
- $coin.rec_{K}(coffee.\overline{ccup}.coin.K + tea.\overline{tcup}.coin.K)$
- $\operatorname{rec}_{K}(\operatorname{coin.coffee.}\overline{\operatorname{ccup}}.K + \operatorname{coin.tea.}\overline{\operatorname{tcup}}.K)$
- Question: which of these machines can we safely consider equivalent?
- Note that these machines have all the same traces.

What equivalence for CCS?

- Define in CCS a semaphore with initial value *n*
- Show that maximal trace equivalence is not a congruence in CCS. By maximal traces here we mean the traces of all possible (finite or infinite) maximal runs.
